OS CASREACT 110:195133

AB The catalysts with lasting activity are prepared by (A) mech. mixing, in the
absence of water, of Al fluoride prepared at <400° and a transition
metal compound of Co, Cr, Fe, Mn, Ni, Ti, or V; and (B) contacting the
resulting mixture with sufficient anhydrous HF to convert the transition metal
compound to a transition metal fluoride. Thus, slowly adding 200 g Al(OH)₃
to 400 g 47-52% HF in 1600 mL H₂O, maintaining the temperature at 60°,
keeping at 60° overnight and drying gave AlF₃, which was mixed with
3.2 % FeCl₃, heated to 250°, treated with HF for 1 h, heated to
400° with continuous feed of HF for another hour, and cooled under
N to 250° to obtain the desired catalyst. The catalyst when used
for the title reaction lasted for 34.5 h before losing >10% of its
activity.

AB Ethylene is reacted with CCl_4 in the presence of a phosphite ester [especially $\text{P}(\text{OEt})_3$ or $\text{P}(\text{OBu})_3$] and powdered Fe catalyst to yield 1,1,1,3-tetrachloropropane (I). Optionally, added FeCl_3 may be present. The powdered Fe is especially electrolytic Fe powder or H-reduced Fe powder. In an autoclave at 90-110 psig C_2H_4 , CCl_4 .apprx.900, $\text{P}(\text{OEt})_3$ 5.5, electrolytic Fe powder 7.5, and FeCl_3 1.174 g were reacted at 95°, resulting in 75.9% I and 21.2% unreacted CCl_4 in the product, corresponding to 96.3% yield of I.

AB Photoreaction of MCO_n (M = Fe, Cr, Mo, W) with CCl₄ in the presence of PPh₃ was investigated by ESR. Substitution of CO by PPh₃ led to the increase of the yield and activity of the metal-containing transients responsible for the generation of the organic radicals. During photolysis of substituted carbonyls of Cr, Mo and W in general cleavage of the metal-CO and not the metal-PPh₃ bond occurred.

 AB The title reaction in the presence of varying amounts of FeCl_2 hydrate, $\text{Fe} + \text{HCl}$, $\text{FeCl}_2\text{-FeCl}_3$, or $\text{Fe}(\text{CO})_5$ was studied for CCl_3R [$\text{R} = \text{CHCl}_2, \text{CH}_2\text{Cl}, (\text{CH}_2)_2\text{Cl}, \text{CHCl}(\text{CH}_2)_2\text{Cl}, \text{CCl}_2(\text{CH}_2)_3\text{Cl}$]. Addition of such compds., with 4th Cl in terminal position, to C_2H_4 occurred readily in iso- PrOH in the presence of either $\text{Fe}(\text{CO})_5$ alone or mixed with Fe chlorides or by the action of a steel plate and a small amount of HCl . Similarly facile was the reaction of 1,1,1-trichloroalkanes. In 1,1,1,2- or 1,1,1,2,2-polychloroalkanes, however, dechlorination took place that led to di- and trichloroalkenes, resp. In the ease of such loss of Cl the decreasing tendency follows the series $\text{CCl}_3\text{CCl}_2\text{R}, \text{CCl}_3\text{CHClR}, \text{CCl}_3\text{CH}_2\text{Cl}$, and $\text{CCl}_3\text{CHCl}_2$. The ease of addition to C_2H_4 is the opposite of the above order.

AB The yields of products formed by the title reaction of PhSH and BuSH in the presence or absence of $\text{Fe}(\text{CO})_5$, FeCl_3 , or azobisisobutyronitrile were reported for reactions run at 75° or 140°. At the lower temperature the tetrachloride acts as inert diluent only and the RSH addition to the olefin is wholly inhibited by $\text{Fe}(\text{CO})_5$. At 140° the thiols reduce the tetrachloride to 1,1,3-trichloropropane and the effectiveness of $\text{Fe}(\text{CO})_5$ as an inhibitor of radical addition of RSH to olefins drops.

AB cf. CA 61, 4196h; 63, 16201c. The reaction between C₂H₄ and CCl₄ was initiated efficiently by organic peroxide-reducing agent-metal carboxylate catalyst systems at relatively low temperature. The reducing agent was benzoin and an amine such as aminoethylethanolamine or mono-, di-, or triethanolamine. For example, 1 + 10⁻³, 1 + 10⁻³, and 1 + 10⁻⁴ mole, resp., of Bz₂O₂, (I) benzoin, and metal (Fe, Pb, Zn, Co, Ni, or Mn) naphthenate were added to 1 mole of CCl₄, and C₂H₄ was bubbled into the reaction mixture at 50° for several hrs. The reaction rate was estimated from the rate of C₂H₄ consumption measured with a gas buret. The reaction products were analyzed by gas chromatography and substantially no compds. other than 1,1,1,3-tetrachloropropane were detected. Among the metal naphthenates tested, Fe naphthenate (II) was by far the most effective, while the kinds of acid groups of the Fe carboxylates had little effect on the effectiveness of the catalyst systems. The effectiveness of different kinds of organic peroxides was tested and it was found that lauroyl peroxide was the most effective, while cumene hydroperoxide was completely ineffective in the organic peroxides-benzoin-II catalyst systems. The reaction rate was proportional to the concentration of the organic peroxide, e.g. dicumyl peroxide (III), in

the concentration range (III/CCl₄ mole ratio) 1.0-2.0 + 10⁻³ with the ratios benzoin/III = 1:1 and II/III = 0.1:1 and at 50°. The effects of the concns. of benzoin and II were also investigated. The apparent activation energy for the reaction calculated from the temperature dependence of the

reaction rate was 6.4 or 8.5 kcal./mole when III or I, resp., was combined with benzoin and II. The value for the catalyst system I-triethanolamine-II was 7.5 kcal./mole. A considerable reaction rate was obtained even in the absence of I or II from the I-triethanolamine-II system and there seems to be an additivity between the reaction rates with both binary catalyst systems that gives the rate with the ternary catalyst system.

 AB cf. CA 55, 24539d. CCl₄ is added to olefins and vinylic monomers under the catalytic influence of iron (II, III) or copper (I, II) chloride, in a variety of solvents at 70-145°. Copper chloride completely suppresses telomerization. A free-radical chain mechanism is proposed for the addition in which metal chloride participates in the propagation as a chlorine atom transfer agent, thereby much enhancing the apparent reactivity of CCl₄ ("redox-transfer"). Exptl. support for this mechanism is presented. The reaction with but-2-ene gives a mixture of 1:1 diastereoisomeric adducts, the composition of which changes with catalyst, and, for copper catalysis, also with the solvent and with the excess of chloride ion. cis- and trans-But-2-ene give the same ratio of diastereoisomers. The initiation mechanism is discussed. At 82°, ferric chloride induces addition of CCl₄ to but-2-ene only in the presence of a reducing agent. This enables the estimation of the kinetic chain length, which has a much larger value than for a peroxide-induced reaction.

AB Telomers formed by the reaction between CCl₄ as telogen and an

α -olefinic compound as taxogen may be prepared using an organic amine or ammonia as primary catalyst and cupric or ferrous salts as secondary catalyst. A sequestering agent such as ethylenediaminetetraacetic acid may also be added. The telomerization may be performed either in aqueous or in anhydrous medium. Safety hazards involved in the use of conventional type catalysts (benzoyl peroxide, azo compds.) are thus eliminated. The 12 examples given include the preparation of $\text{Cl}(\text{CH}_2\text{CH}_2)_n\text{CCl}_3$ ($n = 1$ through 5) and 1,1,1,3-tetrachloro-n-nonane.

AB cf. C.A. 47, 3789c. The CCl_3 group in polychloroalkanes is inert toward nucleophilic agents. 1,1,1-Trichloropentane does not react with NH_3 in EtOH even at 160° or liquid NH_3 at 140° , with NaI, or $\text{NaHC}(\text{CO}_2\text{Et})_2$. Other terminal trichloroalkanes give the same result. In $\alpha,\alpha,\alpha,\omega$ -tetrachloroalkanes only the terminal lone Cl reacts with nucleophilic agents. Thus NaI in Me_2CO reacts with 1,1,1,5-tetrachloropentane yielding 90% 1,1,1-trichloro-5-iodo-pentane, b1.5 $78-9^\circ$, n_{D}^{20} 1.5480, d_{20} 1.8086; the product is readily converted to the cyano derivative by treatment with KCN. Reaction of KOAc with 1,1,1,5-tetrachloropentane in hot AcOH 18 h. in presence of a little KI gave 86% 1,1,1-trichloro-5-acetoxypentane, b3.5 $99-100^\circ$, n_{D}^{20} 1.4700, d_{20} 1.2859; this was readily converted to 5,5,5-trichloro-1-pentanol, b10 $112-12.5^\circ$, n_{D}^{20} 1.4897, d_{20} 1.3431; other nucleophilic agents give similar results. Electrophilic agents attack the CCl_3 group preferentially (cf. C.A. 49, 2298b); the group being resistant to hydrolysis in basic solution, is rapidly attacked by acid solns. and in concentrated H_2SO_4 readily yields the CO_2H group. While CCl_3 group does not display Cl exchange for Br in presence of HBr it does so in the presence of electrophilic AlCl_3 . Passage of HBr into 1,1,1-trichloropentane at $4-5^\circ$ in the presence of a little AlCl_3 gave a good yield of 1,1,1-tribromopentane, b8 $85-6^\circ$, n_{D}^{20} 1.5390, d_{20} 1.9882. Similarly 1,1,1,5-tetrachloropentane yields 1,1,1-tribromo-5-chloropentane, b2 $101-2^\circ$, n_{D}^{20} 1.5655, d_{20} 2.0902. The cleavage of HCl from 1,1,1,2-tetrachloropentane by H_2SO_4 begins only at $140-60^\circ$; similar behavior is seen in 1,1,1,2,5-pentachloropentane. The action of FeCl_3 leads to HCl loss from 1,1,1,5-tetrachloropentane at $30-50^\circ$; 1,1,1,2,5-pentachloropentane requires $100-20^\circ$, yielding 1,1,2,5-tetrachloro-1-pentene, b8 $92-3^\circ$, n_{D}^{20} 1.5113, d_{20} 1.4121. Addition of Cl with cooling to 1,1-dichloro-1-pentene and 1,1,5-trichloro-1-pentene gave, resp., 1,1,1,2-tetrachloropentane, b8 $72-3^\circ$, n_{D}^{20} 1.4825, d_{20} 1.3339, and 1,1,1,2,5-pentachloropentane, b12 $121-2^\circ$, n_{D}^{20} 1.5135, d_{20} 1.4807. Action of free radical type reagents was examined in the action of 1,1,1,5-tetrachloropentane with PhMgBr in the presence of CoCl_2 , with Raney Ni and powdered Cu. In all cases the reaction took place at the CCl_3 group. No reaction took place with PhMgBr alone; in the presence of CoCl_2 there was formed a mixture of products from which were isolated Ph_2 and 1,5,5,6,6,10-hexachlorodecane (I); the products evidently arise from radical attack and the latter is accounted for by formation of $\text{Cl}(\text{CH}_2)_4\text{CCl}_2$ radical. Action of Raney Ni in EtOH gave, after 2 h. reflux, 37% I; powdered Cu gave the same result. While heterolytic reactions in terminal CH_2Cl group by nucleophilic agents, and in CCl_3 group by electrophilic agents proceeds well and give few

10/648,709

byproducts, the homolytic reactions of CCl₃ group are apt to give product mixture. The higher polychloroalkanes behave in the same way as the above-described pentanes. However 1,1,1,3-tetrachloropropane reacts differently; with NaCN, Na₂S or other nucleophilic agents it does not exchange Cl in the CH₂Cl group but undergoes HCl cleavage forming the olefin derivs.

AB	CCl ₃ (CH ₂) ₂ Cl (I) heated with Fe, Cu, or Al at 100-150° in the presence of H ₂ O yields CCl ₃ (CH ₂) ₄ CCl ₃ (II), m. 108-9° (from EtOH). Thus 30 cc. I, 25 g. powdered Fe, and 150 cc. H ₂ O are refluxed with stirring for 28 hrs., the mixture extracted with Et ₂ O, and the Et ₂ O evaporated to leave an oily residue from which II crystallizes in colorless needles (20% yield). II is useful as plasticizer for chlorinated resins and as intermediate for adipic acid.
